Overview
With the rapid urbanization and changing lifestyles people around the world are consuming more energy-dense foods that are high in saturated fats, trans-fats, sugars and salt. Highly processed foods are increasing in availability and becoming more affordable. At the same time, as their eating patterns shift, people are consuming less fruit vegetables and dietary fibre (such as whole grains), that are key components of a healthy diet.

Salt is the main source of sodium and increased consumption is associated with hypertension and increased risk of heart and stroke whereas fruits and vegetables contain potassium, which contribute to reduce blood pressure.

Salt in the diet can come from processed foods, either because they are particularly high in salt (such as ready meals, processed meats like bacon, ham, cheese, salty snack foods, and instant noodles, among others) or because they are consumed frequently in large quantities (such as bread and processed cereal products), other than added salt during cooking or at the table (soy sauce, fish sauce and table salt).

Sodium is also found naturally in a variety of foods, such as milk, meat and shellfish and food additives contained in sodium glutamate.

However, some manufacturers are reformulating recipes to reduce the salt content of their products and consumers should read food labels and choose products low in sodium.

**WHO Recommendations for salt reduction**
- For adults: WHO recommends that adults consume less than 5 g (just under a teaspoon) of salt per day.
- For children: WHO recommends that the recommended maximum intake of salt for adults be adjusted downward for children aged 2 to 15 years based on their energy requirements relative to those of adults. This recommendation for children is not applicable to the period of exclusive breastfeeding (0–6 months) or complementary feeding with continued breastfeeding (6–24 months).

All salt that is consumed should be iodized or “fortified” with iodine, a mineral essential for healthy brain development in the foetus and young child, and optimizing mental function in general.

**Effects of Salt, sodium and potassium in human body**
- Sodium is an essential nutrient necessary for maintenance of plasma volume, acid-base balance, transmission of nerve impulses and normal cell function.
- Excess sodium intake is associated with adverse health outcomes, including increased blood pressure.
- Potassium is an essential nutrient needed for maintenance of total body fluid volume, acid and electrolyte balance, and normal cell function.
Increased potassium intake as opposed to sodium reduced systolic and diastolic blood pressure in adults.

How to reduce salt in diets

Government policies and strategies should create environments that enable populations to consume adequate quantities of safe and nutritious foods that make up a healthy diet including low salt.

Key broad strategies for salt reduction include:

- Government policies - including economic policies and regulation to ensure food manufacturers and stores produce healthier foods or make healthy products available and affordable
- Collaboration with the private sector to improve the availability and accessibility of low-salt products
- Consumer awareness through social marketing to raise awareness of the need to reduce salt consumption
- Promotion of “healthy food” settings such as schools, workplaces and communities
- Monitoring of population salt intake, sources of salt in the diet and consumer knowledge, attitudes and behaviours relating to salt to inform policy decisions

Salt reduction programmes and programmes that promote fortification with micronutrients of salt can complement each other.

Salt consumption at home can be reduced by measures such as:

- Addition of low/no salt during the preparation of food
- Non availability of salt shaker on the table
- Limiting the consumption of salty snacks
- Choosing products with lower sodium content

Other local practical actions to reduce salt intake include:

- integrating salt reduction into the training curriculum of food handlers
- Removal of salt shakers and soy sauce from tables in restaurants
- Introduction of product or shelf labels making it clear that certain products are high in sodium
- Education of children and provision of a supportive environment for children so that they start early with adopting low salt diets

Actions by the food industry should include:

- incremental reduction salt in products over time so that consumers adapt to the taste and don’t switch to alternative products
- consumer awareness activities in food outlets
- labelling sodium content of foods and meals

Response adopted by WHO

WHO guidelines on sodium and potassium provide thresholds for healthy intake. The guidelines also outline measures for improving diets and preventing NCDs in adults and children.

The “Global Strategy on Diet, Physical Activity and Health” was adopted in 2004 by the World Health Assembly (WHA). It calls on governments, WHO, international partners, the private sector and civil society to take action at global, regional and local levels to support healthy diets and physical activity.

In 2011, world leaders committed to reducing people’s exposure to unhealthy diets and the commitment was made through a Political Declaration of the High-level Meeting of the United Nations General Assembly on Prevention and Control of NCDs.

In 2013, the WHA agreed on 9 global voluntary targets for the prevention and control of NCDs, which include a halt to the rise in diabetes and obesity and a 30% relative reduction in the intake of salt by 2025. The “Global Action Plan for the Prevention and Control of Noncommunicable Diseases 2013-2020” gives guidance and a menu of policy options for Member States, WHO and other UN agencies to achieve the targets.
